

GRADED BETTI NUMBERS OF COHEN-MACAULAY MODULES AND THE MULTIPLICITY CONJECTURE

MATS BOIJ AND JONAS SÖDERBERG

ABSTRACT. We give conjectures on the possible graded Betti numbers of Cohen-Macaulay modules up to multiplication by positive rational numbers. The idea is that the Betti diagrams should be non-negative linear combinations of *pure* diagrams. The conjectures are verified in the cases where the structure of resolutions are known, i.e., for modules of codimension two, for Gorenstein algebras of codimension three and for complete intersections. The motivation for the conjectures comes from the Multiplicity conjecture of Herzog, Huneke and Srinivasan.

1. INTRODUCTION

The graded Betti numbers of Cohen-Macaulay algebras and modules are invariants that have been used in many different ways. In some special cases, there are structure theorems that tell us precisely what the graded minimal free resolutions can be, as in the case of the Hilbert-Burch theorem for Cohen-Macaulay algebras of codimension two or the Buchsbaum-Eisenbud theorem for Gorenstein algebras of codimension three [2]. There have been some attempts to develop such structure theorems more generally [11, 10], but so far, there are no more strong results in this direction. For some combinatorially defined algebras, like the Stanley-Reisner rings of simplicial polytopes, there are direct connections between the graded Betti numbers and topological invariants. In recent years, the Multiplicity conjecture of Herzog, Huneke and Srinivasan [6, 8] has been inspiring a lot of interesting results on the possible graded Betti numbers. The conjecture gives lower and upper bounds for the multiplicity of a graded algebra in terms of the lowest degrees and highest degrees where the Betti numbers are non-zero. The conjecture has been verified in a number of interesting cases, including the ones mentioned above where the structure of the minimal free resolution is known (see Herzog and Srinivasan [6], Migliore, Nagel and Römer [14, 13], Miró-Roig [15] and Kubitzke and Welker [9]). However, the meaning of the conjecture itself has been a bit mysterious, since the multiplicity of an algebra is a very coarse invariant, while the graded Betti numbers are much finer.

We will now argue for a stronger conjecture on the possible graded Betti numbers of Cohen-Macaulay algebras and modules, which is easily seen to imply the multiplicity conjecture in this case. The Multiplicity conjecture was inspired by the calculation of the multiplicity, $e(A)$, of an algebra with a *pure resolution*, i.e., a resolution where each component is homogeneous, of degree d_i , for $i = 1, 2, \dots, p$. This calculation shows that the multiplicity is given by the very

simple formula

$$e(A) = \frac{d_1 d_2 \cdots d_p}{p!}.$$

The Multiplicity conjecture gives the same expression as the lower and upper bound for any graded algebra, where the degrees are replaced by the lowest and highest degrees that appear in each component of the minimal free resolution.

In our conjecture, Conjecture 2.4, the pure resolutions also play a central role. We look at the possible Betti numbers of graded Cohen-Macaulay algebras, or modules, as a subset of an integral lattice, which sits inside a vector space over the rational numbers. By taking direct sums of modules, we see that this subset is closed under addition. If we also normalize so that the first Betti number, β_0 , is equal to one, the subset obtained will be closed under convex combinations, i.e., linear combinations with non-negative rational coefficients. The Betti numbers of the pure resolutions will be in some sense extremal, and the idea is that they will actually be the only vertices of the convex set described above. The pure resolutions will be partially ordered in a natural way which is compatible with the multiplicity given by the formula above. This shows that the conjecture implies the multiplicity conjecture, as will be made more precise in Proposition 2.8.

In addition to this we conjecture (Conj. 2.10) that the convex set also has a very nice structure of a simplicial polytope which implies that the non-negative linear expansion of a Betti diagram into pure diagrams is unique if the pure diagrams included have to be totally ordered. We are able to prove our conjectures in a few, but interesting cases, where the set of possible Betti diagrams is actually known. This includes the codimension two Cohen-Macaulay modules generated in a single degree (Thm. 3.4), codimension three Gorenstein algebras (Thm. 4.4) and complete intersections in any codimension (Thm. 4.3).

There is still much to be done in order to prove the conjectures, or even to give more evidence for them, in a greater generality. For example, in codimension three and higher, it is not known whether there are modules with a pure resolution for each set of admissible degrees, $d_1, d_2, \dots, d_p$. Furthermore, it would be much more satisfactory to have proofs that use some kind of deformation argument, showing that the modules actually split into sums of modules with pure resolutions somewhere in the parameter space of Cohen-Macaulay modules with fixed graded Betti numbers.

2. THE SET OF NORMALIZED BETTI NUMBERS

Let $R = k[x_1, x_2, \dots, x_n]$ be the polynomial ring in n variables over a field k . Consider R as a graded ring by giving each x_i degree one. All R -modules in this article are assumed to be finitely generated and graded. The d -th twist of an R -module M , denoted by $M(d)$, is defined by $M(d)_i = M_{i+d}$. If the R -module M has a minimal free resolution given by

$$0 \rightarrow \bigoplus_j R(-j)^{\beta_{p,j}} \rightarrow \cdots \rightarrow \bigoplus_j R(-j)^{\beta_{0,j}} \rightarrow M \rightarrow 0$$

then $\beta_{i,j}(M) = \beta_{i,j}$ are the graded Betti numbers of M and the matrix $\beta(M)$ with entries $\beta(M)_{i,j} = \beta_{i,j}(M)$ is called the *Betti diagram* of M . From the

resolution we also see that the projective dimension of M is p and when M is Cohen-Macaulay it is equal to the codimension, that is, $\dim R - \dim M = p$. Furthermore, if M is Cohen-Macaulay then the h -vector of M is the Laurent polynomial $h_M(t) \in \mathbb{Z}[t, t^{-1}]$ given by

$$h_M(t) = \frac{S_M(t)}{(1-t)^p},$$

where $S_M(t) = \sum_{i,j} (-1)^i \beta_{i,j}(M) t^j$. The multiplicity of M can be calculated from its h -vector by

$$e(M) = h_M(1).$$

The fact that the polynomial $S_M(t)$ is divisible by $(1-t)^p$ is equivalent to the fact that

$$\frac{d^i}{dt^i} S_M(1) = 0$$

for $i = 0, 1, \dots, p-1$. This translates to the system of linear equations

$$(2.1) \quad \begin{cases} \sum_{i,j} (-1)^i \beta_{i,j} &= 0 \\ \sum_{i,j} (-1)^i j \beta_{i,j} &= 0 \\ &\vdots \\ \sum_{i,j} (-1)^i j^{p-1} \beta_{i,j} &= 0 \end{cases}$$

whose set of solutions contains all possible Betti numbers of graded Cohen-Macaulay modules of codimension p . This observation leads to the following definition.

Definition 2.1. For any strictly increasing sequences of integers $\underline{d} = (d_0, \dots, d_p)$ and $\bar{d} = (\bar{d}_0, \dots, \bar{d}_p)$, let $V_{\underline{d}, \bar{d}}$ be the vector space over the rational numbers of all matrices $(\beta_{i,j})$ such that:

- a) $\beta_{i,j}$ is a solution to the system of linear equations (2.1),
- b) $\beta_{i,j} = 0$ whenever $j < \underline{d}_i$ or $j > \bar{d}_i$ (or $i < 0$ or $i > p$).

An element $D = (\beta_{i,j})$ in $V_{\underline{d}, \bar{d}}$ will be called a *diagram* and we define the h -vector, $h_D(t)$, and multiplicity, $e(D)$, of a diagram from the polynomial $S_D(t) = \sum_{i,j} (-1)^i \beta_{i,j} t^j$ in the same way as we did for a module above. Furthermore, we say that D has codimension p .

Let M be a Cohen-Macaulay R -module of codimension p . The *maximal and minimal shifts* of degree i of M are defined by $\bar{d}_i(M) = \max\{j \mid \beta_{i,j}(M) \neq 0\}$ and $\underline{d}_i(M) = \min\{j \mid \beta_{i,j}(M) \neq 0\}$, respectively. It is well known that when M is Cohen-Macaulay then the sequences $\bar{d}(M) = (\bar{d}_0(M), \bar{d}_1(M), \dots, \bar{d}_p(M))$ and $\underline{d}(M) = (\underline{d}_0(M), \underline{d}_1(M), \dots, \underline{d}_p(M))$ are strictly increasing. Using the notation introduced in Definition 2.1 we get that the Betti diagram of M , $\beta(M)$, is an element in the vector space $V_{\underline{d}(M), \bar{d}(M)}$.

Let $\underline{d}$ and $\bar{d}$ be two strictly increasing sequences of integers and denote by $B_{\underline{d}, \bar{d}}$ the set of Betti diagrams in $V_{\underline{d}, \bar{d}}$. As mentioned in the introduction we have that $\beta(M_1) + \beta(M_2) = \beta(M_1 \oplus M_2)$ so we see that $\beta(M_1) + \beta(M_2)$ is in $B_{\underline{d}, \bar{d}}$ if $\beta(M_1)$ and $\beta(M_2)$ are, for any Cohen-Macaulay R -modules M_1 and M_2 . By normalizing the Betti diagrams in $B_{\underline{d}, \bar{d}}$ in such a way that $\beta_0 = \sum_j \beta_{0,j} = 1$ we

get a subset of $V_{\underline{d}, \bar{d}}$ closed under convex combinations over the rational numbers. By describing this convex, and in fact bounded, subset of the vector space $V_{\underline{d}, \bar{d}}$ we get a description of the possible Betti diagrams up to multiplication by an integer.

Definition 2.2. Let M be a Cohen-Macaulay R -module. The numbers $\bar{\beta}_{i,j}(M) = \beta_{i,j}(M)/\beta_0$, where $\beta_0 = \sum_j \beta_{0,j}(M)$, will be called the *normalized Betti numbers* of M and the corresponding diagram $\bar{\beta}(M) = \beta(M)/\beta_0$ the *normalized Betti diagram* of M . We denote by $\bar{B}_{\underline{d}, \bar{d}}$ the set of all normalized Betti diagrams in $V_{\underline{d}, \bar{d}}$.

2.1. Pure diagrams. The main purpose of this section is to give a conjectural description of the set of normalized Betti diagrams, $\bar{B}_{\underline{d}, \bar{d}}$, as the convex hull of the pure diagrams in $V_{\underline{d}, \bar{d}}$ and we begin by explaining the notion of a pure diagram.

We say that a R -module M has a *pure resolution* of type $d = (d_0, d_1, \dots, d_p)$ if its minimal free resolution has the form

$$0 \rightarrow R(-d_p)^{\beta_p} \rightarrow \dots \rightarrow R(-d_0)^{\beta_0} \rightarrow M \rightarrow 0.$$

Herzog and Kühn showed in [5] that the Betti numbers of a pure resolution of a Cohen-Macaulay algebra are determined by its type and Huneke and Miller computed in [8] the multiplicity of such an algebra, also in terms of its type. These two results can be extended to Cohen-Macaulay R -modules, see [13], and what follows is a short explanation of how this can be done.

Given a pure resolution we may try to solve system (2.1) for the unknowns $\beta_0, \beta_1, \dots, \beta_p$. Before we do that we will add one equation. We have

$$\frac{d^p}{dt^p} S_M(t) = \frac{d^p}{dt^p} h_M(t)(1-t)^p = \sum_{i=0}^p \binom{p}{i} (-1)^i \frac{p!(1-t)^{p-i}}{(p-i)!} \frac{d^{p-i}}{dt^{p-i}} h_M(t)$$

where the second equality follows by expanding its left-hand side with the product rule for derivation. With $t = 1$ this equation yields $\frac{d^p}{dt^p} S_M(1) = (-1)^p p! h_M(1) = (-1)^p p! e(M)$. Since, on the other hand, $\frac{d^p}{dt^p} S_M(1) = \frac{d^p}{dt^p} \sum_{i,j} (-1)^i \beta_{i,j}(M) t^j = \sum_{i,j} (-1)^i j^p \beta_{i,j}$, where we have used (2.1) to get rid of the the lower powers of j , we get

$$\sum_{i,j} (-1)^i j^p \beta_{i,j} = (-1)^p p! e(M).$$

Adding this equation to the system (2.1) yields

$$\begin{pmatrix} 1 & -1 & \dots & (-1)^p \\ d_0 & -d_1 & \dots & (-1)^p d_p \\ \vdots & \vdots & \vdots & \vdots \\ d_0^{p-1} & -d_1^{p-1} & \dots & (-1)^p d_p^{p-1} \\ d_0^p & -d_1^p & \dots & (-1)^p d_p^p \end{pmatrix} \begin{pmatrix} \beta_0 \\ \beta_1 \\ \vdots \\ \beta_{p-1} \\ \beta_p \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ \vdots \\ 0 \\ (-1)^p p! e(M) \end{pmatrix}$$

and by solving this linear system of equations with Cramer's rule and the Vandermonde determinant we get

$$\beta_i = (-1)^{i+1} p! e(M) \prod_{k \neq i} \frac{1}{d_k - d_i}.$$

Hence

$$e(M) = \beta_0 \frac{1}{p!} \prod_{k=1}^p (d_k - d_0)$$

and

$$\beta_i = \beta_0 (-1)^{i+1} \prod_{\substack{k \neq i \\ k \neq 0}} \frac{d_k - d_0}{d_k - d_i}.$$

Note that this solution exists for any strictly increasing sequence of integers $(d_0, d_1, \dots, d_p)$, even if it is not given by the type of a pure resolution.

Definition 2.3. For any strictly increasing sequence of integers $d = (d_0, d_1, \dots, d_p)$, the matrix $\pi(d)$ defined by

$$\pi(d)_{i,j} = \begin{cases} (-1)^{i+1} \prod_{\substack{k \neq i \\ k \neq 0}} \frac{d_k - d_0}{d_k - d_i} & \text{when } j = d_i, \\ 0 & \text{when } j \neq d_i, \end{cases}$$

will be called a *pure diagram*. The partial order on sequences of integers of length $p+1$, given by $d \leq d'$ whenever $d_i \leq d'_i$ for $i = 0, 1, \dots, p$, defines a partial order on the pure diagrams, that is, $\pi(d) \leq \pi(d')$ whenever $d \leq d'$. Furthermore, for any two strictly increasing sequences, $\underline{d}$ and $\overline{d}$, of length $p+1$ we denote by $\Pi_{\underline{d}, \overline{d}}$ the partially ordered set of all pure diagrams in $V_{\underline{d}, \overline{d}}$, that is, all $\pi(d)$ such that $\pi(\underline{d}) \leq \pi(d) \leq \pi(\overline{d})$.

Note that the multiplicity of a pure diagram, by the above calculation, is given by

$$e(\pi(d)) = \frac{1}{p!} \prod_{i=1}^p (d_i - d_0),$$

and hence that $\pi(d) < \pi(d')$ implies $e(\pi(d)) < e(\pi(d'))$ as long as $d_0 = d'_0$.

We are now ready to state the conjecture describing the set of normalized Betti diagrams $\overline{B}_{\underline{d}, \overline{d}}$.

Conjecture 2.4. *The Betti diagram of any Cohen-Macaulay R -module is a non-negative linear combination of pure diagrams and furthermore, any pure diagram is a rational multiple of the Betti diagram of some Cohen-Macaulay R -module. In other words, $\overline{B}_{\underline{d}, \overline{d}}$ is equal to the convex hull of $\Pi_{\underline{d}, \overline{d}}$.*

Example 2.5. Let $A = k[x, y]/(y^2, xy, y^4)$. The Betti diagram of A is then

$$\beta(A) = \begin{pmatrix} 1 & - & - \\ - & 2 & 1 \\ - & - & - \\ - & 1 & 1 \end{pmatrix}$$

where we have used the convention of writing the entry $\beta_{i,j}(A)$ in column i and row $j - i$. (The reason for shifting the rows in this way is simply to save space.)

Conjecture 2.4 states that any Betti diagram of a Cohen-Macaulay R -module allows a non-negative linear expansion into pure diagrams and we see that this holds for the Betti diagram $\beta(A)$ since

$$\beta(A) = \frac{1}{2} \begin{pmatrix} 1 & - & - \\ - & 3 & 2 \\ - & - & - \\ - & - & - \end{pmatrix} + \frac{3}{10} \begin{pmatrix} 1 & - & - \\ - & 5/3 & - \\ - & - & - \\ - & - & 2/3 \end{pmatrix} + \frac{1}{5} \begin{pmatrix} 1 & - & - \\ - & - & - \\ - & - & - \\ - & 5 & 4 \end{pmatrix},$$

that is,

$$\beta(A) = \frac{1}{2}\pi(0, 2, 3) + \frac{3}{10}\pi(0, 2, 5) + \frac{1}{5}\pi(0, 4, 5).$$

The conjecture also states that some integer multiple of any pure diagram is the Betti diagram of a Cohen-Macaulay R -module. We will now see that this is true for the pure diagrams in this example. The pure diagrams $\pi(0, 2, 3)$ and $\pi(0, 4, 5)$ are the Betti diagrams of $k[x, y]/\mathfrak{m}^2$ and $k[x, y]/\mathfrak{m}^4$ where $\mathfrak{m} = (x, y)$. The pure diagram $\pi(0, 2, 5)$ have non-integer entries so it needs to be multiplied by some integer. Let I and J be the ideals of $k[x, y]$ given by $I = (x^4, x^2y^2, y^4)$ and $J = (x^6, x^3y^3, y^6)$ and let M be the $k[x, y]$ -module $M = I/J$. Then the Betti diagram of M is, after twisting its degrees by 4, $\beta(M(4)) = 3 \cdot \pi(0, 2, 5)$.

We will now show that any maximal chain of pure diagrams is a vector space basis of $V_{\underline{d}, \bar{d}}$. Hence, we know that any Betti diagram is a linear combination of pure diagrams while Conjecture 2.4 states that there is a linear combination with non-negative coefficients. A natural question now is if the pure diagrams in a non-negative linear expansion of a Betti diagram always can be chosen to be a maximal chain. We make a closer analysis of this question in Section 2.3 where we conjecture this to be true (Conjecture 2.10).

Proposition 2.6. *The elements of any chain of pure diagrams are linearly independent.*

Proof. Let $\pi(d_1) < \pi(d_2) < \dots < \pi(d_t)$ be a chain of pure diagrams. Then there is an integer k such that $(d_1)_k < (d_2)_k \leq (d_3)_k \leq \dots \leq (d_t)_k$ and hence $(\pi(d_1))_{k, (d_1)_k} \neq 0$ and $(\pi(d_i))_{k, (d_1)_k} = 0$ for all $2 \leq i \leq t$. This shows that $\pi(d_1)$ is not in the span of the pure diagrams $\pi(d_2), \pi(d_3), \dots, \pi(d_t)$. Now we may assume by induction that the pure diagrams in the shorter chain $\pi(d_2) < \pi(d_3) < \dots < \pi(d_t)$ are linearly independent which finishes the proof. $\square$

Proposition 2.7. *For any two strictly increasing sequences of non-negative integers $\underline{d} = (\underline{d}_0, \underline{d}_1, \dots, \underline{d}_p)$ and $\bar{d} = (\bar{d}_0, \bar{d}_1, \dots, \bar{d}_p)$, the dimension of $V_{\underline{d}, \bar{d}}$ is $1 + \sum_{i=0}^p (\bar{d}_i - \underline{d}_i)$ and any maximal chain in $\Pi_{\underline{d}, \bar{d}}$ is a basis of $V_{\underline{d}, \bar{d}}$.*

Proof. If D is a diagram in $V_{\underline{d}, \bar{d}}$ then D has at most $\sum_{i=0}^p (\bar{d}_i - \underline{d}_i + 1) = p + 1 + \sum_{i=0}^p (\bar{d}_i - \underline{d}_i)$ non-zero entries. Let $j_0, j_1, \dots, j_t$ be the set of all integers j such that $\underline{d}_i \leq j \leq \bar{d}_i$ for some i , and note that $t \geq p$. Then we can write

equation (2.1) as

$$\begin{cases} \alpha_{j_0} + \alpha_{j_1} + \dots + \alpha_{j_t} = 0 \\ j_0 \alpha_{j_0} + j_1 \alpha_{j_1} + \dots + j_t \alpha_{j_t} = 0 \\ \vdots \\ j_0^{p-1} \alpha_{j_0} + j_1^{p-1} \alpha_{j_1} + \dots + j_t^{p-1} \alpha_{j_t} = 0 \end{cases}$$

where $\alpha_{j_k} = \sum_i (-1)^i \beta_{i,j_k}$. This linear system has maximal rank by the Vandermonde determinant and since $t \geq p$ this rank is p . We get $\dim V_{\underline{d}, \bar{d}} = 1 + \sum_{i=0}^p (\bar{d}_i - \underline{d}_i)$.

Let F be a maximal chain in $\Pi_{\underline{d}, \bar{d}}$. The elements of F are linearly independent by Proposition 2.6. To see that they span $V_{\underline{d}, \bar{d}}$ it is enough to prove that the length of F is equal to the dimension of $V_{\underline{d}, \bar{d}}$. Let $\pi(\underline{d}) = \pi(d_1) < \pi(d_2) < \dots < \pi(d_n) = \pi(\bar{d})$ be a maximal chain. Let the degree of d_i be defined by $\deg d_i = \sum_k (d_i)_k$. Since the chain is maximal we have, for each i , that d_i and d_{i+1} differ in precisely one position and that they differ by one in that position, that is $\deg d_{i+1} - \deg d_i = 1$. We get $\deg \bar{d} - \deg \underline{d} = \sum_{i=1}^{n-1} \deg d_{i+1} - \deg d_i = n - 1$ and hence the length of the chain is $n = 1 + \deg \bar{d} - \deg \underline{d} = \dim V_{\underline{d}, \bar{d}}$. $\square$

2.2. The Multiplicity conjecture. One of the main motivations of Conjecture 2.4 is the Multiplicity conjecture of Herzog, Huneke and Srinivasan (see [8], [6]). Let $A = R/I$ be a Cohen-Macaulay algebra for some ideal I of R , and let $\underline{d} = (\underline{d}_0, \underline{d}_1, \dots, \underline{d}_p)$ and $\bar{d} = (\bar{d}_0, \bar{d}_1, \dots, \bar{d}_p)$ be the minimal and maximal shifts of a minimal free resolution of A , that is, $\underline{d}_i = \min\{j \mid \beta_{i,j}(A) \neq 0\}$ and $\bar{d}_i = \max\{j \mid \beta_{i,j}(A) \neq 0\}$. The Multiplicity conjecture states that

$$\prod_{i=1}^p \underline{d}_i \leq p!e(A) \leq \prod_{i=1}^p \bar{d}_i.$$

Migliore, Nagel and Römer extended this conjecture in [13] by saying that, we have equality in the above equation, below or above, if and only if the resolution of A is pure.

We will now show that this extended Multiplicity conjecture holds for all diagrams in the convex hull of $\Pi_{\underline{d}, \bar{d}}$ and thus that Conjecture 2.4 implies the extended Multiplicity conjecture. This turns out to be an easy consequence of the fact that $\pi > \pi'$ implies $e(\pi) > e(\pi')$ for any pure diagrams π and π' of the same codimension, whose type agree in degree zero.

Proposition 2.8. *Let $\underline{d} = (\underline{d}_0, \underline{d}_1, \dots, \underline{d}_p)$ and $\bar{d} = (\bar{d}_0, \bar{d}_1, \dots, \bar{d}_p)$ be two strictly increasing sequences of integers such that $\underline{d} \leq \bar{d}$. Assume that $\underline{d}_0 = \bar{d}_0 = 0$ and that $D \in V_{\underline{d}, \bar{d}}$ is in the convex hull of $\Pi_{\underline{d}, \bar{d}}$. Then*

$$\prod_{i=1}^p \underline{d}_i \leq p!e(D) \leq \prod_{i=1}^p \bar{d}_i.$$

with equality below or above if and only if D is a pure diagram.

Proof. We have that

$$D = \sum_{\pi \in \Pi_{\underline{d}, \bar{d}}} c_{\pi} \pi$$

for some non-negative rational numbers c_{π} such that $\sum_{\pi \in \Pi_{\underline{d}, \bar{d}}} c_{\pi} = 1$. We get

$$e(D) = \sum_{\pi \in \Pi_{\underline{d}, \bar{d}}} c_{\pi} e(\pi)$$

and hence

$$\min \{e(\pi) \mid \pi \in \Pi_{\underline{d}, \bar{d}}\} \leq e(D) \leq \max \{e(\pi) \mid \pi \in \Pi_{\underline{d}, \bar{d}}\}.$$

Since $\pi < \pi'$ implies that $e(\pi) < e(\pi')$ we get $e(\pi(\underline{d})) \leq e(D) \leq e(\pi(\bar{d}))$ and the inequalities of the proposition follows by applying the formula for the multiplicity of a pure diagram to $e(\pi(\underline{d}))$ and $e(\pi(\bar{d}))$. Furthermore, if $D \neq \pi(\underline{d})$ then the left inequality is strict which shows that we have equality below if and only if D is a pure diagram. In the same way we see that we have equality above if and only if $D = \pi(\bar{d})$. $\square$

2.3. The order complex of $\Pi_{\underline{d}, \bar{d}}$. In this section we will present a conjecture giving the convex hull of $\Pi_{\underline{d}, \bar{d}}$ more structure.

To any partially ordered finite set, *poset* for short, we can associate a simplicial complex. The *order complex* $\Delta(\Pi)$ of the poset Π is simply the set of chains in Π . The chains of Π are thus the *faces* of $\Delta(\Pi)$ and the maximal chains its *facets*. The order complex we are interested in is, of course, $\Delta(\Pi_{\underline{d}, \bar{d}})$ and we will begin by describing a geometric realization, in the vector space $V_{\underline{d}, \bar{d}}$, of this abstract simplicial complex. We then conjecture that the convex hull of $\Pi_{\underline{d}, \bar{d}}$ is equal to this geometric realization of $\Delta(\Pi_{\underline{d}, \bar{d}})$.

Since the elements in a maximal chain in $\Pi_{\underline{d}, \bar{d}}$, by Proposition 2.6, are linearly independent, the convex hull of these elements is a geometric realization of the abstract simplex corresponding to the chain. We will now see that the union of these simplices is a geometric realization of the order complex $\Delta(\Pi_{\underline{d}, \bar{d}})$, so we may think of $\Delta(\Pi_{\underline{d}, \bar{d}})$ as sitting in $V_{\underline{d}, \bar{d}}$.

FIGURE 1. $\Pi_{\underline{d}, \bar{d}}$ and $\Delta(\Pi_{\underline{d}, \bar{d}})$ when $\underline{d} = (0, 1, 3)$ and $\bar{d} = (0, 3, 4)$.

Proposition 2.9. *The simplicial complex $\Delta(\Pi_{\underline{d}, \bar{d}})$ has a geometric realization given by the union of the simplices spanned by the maximal chains in $\Pi_{\underline{d}, \bar{d}}$.*

Proof. Let $\pi_1 < \pi_2 < \cdots < \pi_q$ and $\pi'_1 < \pi'_2 < \cdots < \pi'_q$ be two maximal chains in $\Pi_{\underline{d}, \bar{d}}$. It is sufficient to show that any point in the intersection of the two simplices spanned by $\pi_1, \pi_2, \dots, \pi_q$ and $\pi'_1, \pi'_2, \dots, \pi'_q$ is in a common face, spanned by a subset of the common vertices of the two simplices.

Assume that

$$\sum_{i=1}^q a_i \pi_i = \sum_{i=1}^q a'_i \pi'_i,$$

for some non-negative rational numbers $a_1, a_2, \dots, a_q$ and $a'_1, a'_2, \dots, a'_q$. We will now prove that $a_i = a'_i$ for all $0 \leq i \leq q$ and furthermore that $a_i = a'_i = 0$ whenever $\pi_i \neq \pi'_i$.

Assume that this is true for the sub-chains $\pi_1 < \pi_2 < \cdots < \pi_k$ and $\pi'_1 < \pi'_2 < \cdots < \pi'_k$. Then

$$\sum_{i=k+1}^q a_i \pi_i = \sum_{i=k+1}^q a'_i \pi'_i.$$

In what follows we will refer to the integers in the sequence giving the type of a pure diagram as its shifts. Since π_{k+1} is the smallest element in the chain $\pi_{k+1} < \pi_{k+2} < \cdots < \pi_q$ it has a shift in some position unique among the shifts occurring in this position for all the pure diagrams in the chain. Hence it has a non-zero entry in some position where the entry of all other pure diagrams in the chain are zero. The same holds for π'_{k+1} and the chain $\pi'_{k+1} < \pi'_{k+2} < \cdots < \pi'_q$. It follows that if $\pi_{k+1} = \pi'_{k+1}$ then $a_{k+1} = a'_{k+1}$.

If instead $\pi_{k+1} \neq \pi'_{k+1}$, then π_{k+1} and π'_{k+1} are incomparable. This means π_{k+1} has a non-zero entry in a position where the entry of all the pure diagrams in the chain $\pi'_{k+1} < \pi'_{k+2} < \cdots < \pi'_q$ are zero and thus $a_{k+1} = 0$. That $a'_{k+1} = 0$ follows by a symmetric argument. We have shown that the assertion holds for the chains $\pi_1 < \pi_2 < \cdots < \pi_{k+1}$ and $\pi'_1 < \pi'_2 < \cdots < \pi'_{k+1}$. The assertion holds obviously for the empty chains so we can use this as basis for the induction which finishes the proof. $\square$

Note that Proposition 2.9 actually shows that any non-negative linear expansion into a maximal chain is unique, since, after normalization, it will be contained in precisely one of the simplices of $\Delta(\Pi_{\underline{d}, \bar{d}})$.

Conjecture 2.10. *Any non-negative linear combination of pure diagrams is a non-negative linear combination of pure diagrams from the same chain. In other words, the convex hull of $\Pi_{\underline{d}, \bar{d}}$ is equal to the geometric realization of the order complex $\Delta(\Pi_{\underline{d}, \bar{d}})$.*

Conjecture 2.10 leads to an interesting algorithm for deciding whether a diagram, D , has a non-negative linear expansion into pure diagrams, or not. By Conjecture 2.10 this is equivalent to deciding if it has an expansion into a chain of pure diagrams. Assume that

$$D = c_1 \pi(d_1) + c_2 \pi(d_2) + \cdots + c_p \pi(d_p)$$

where $\pi(d_1) < \pi(d_2) < \dots < \pi(d_p)$ is a chain of pure diagrams and $c_1, c_2, \dots, c_p$ are non-negative rational coefficients. Then d_1 is the sequence of minimal shifts of D and c_1 is the largest non-negative integer such that all the entries of $D' = D - c_1\pi(d_1)$ are non-negative. We get

$$D' = c_2\pi(d_2) + \dots + c_p\pi(d_p)$$

and continuing in the same way gives us the chain $\pi(d_1) < \pi(d_2) < \dots < \pi(d_p)$ and the coefficients $c_1, c_2, \dots, c_p$. If D is not a non-negative linear combination of pure diagrams from the same chain then, at some point, the minimal shifts of D' will be a sequence of integers that is not strictly increasing.

Example 2.11. Consider the Betti diagram

$$\beta(A) = \begin{pmatrix} 1 & - & - \\ - & 2 & 1 \\ - & - & - \\ - & 1 & 1 \end{pmatrix}$$

of Example 2.5. We will now apply the algorithm described above to the diagram $\beta(A)$. Its minimal shifts are $(0, 2, 3)$ and following the algorithm we see that $c_1 = \frac{1}{2}$ is the largest non-negative integer such that all entries of $\beta(A) - c_1\pi(0, 2, 3)$ are non-negative. We get

$$D' = \beta(A) - \frac{1}{2}\pi(0, 2, 3) = \begin{pmatrix} 1/2 & - & - \\ - & 1/2 & - \\ - & - & - \\ - & 1 & 1 \end{pmatrix}$$

whose minimal shifts are $(0, 2, 5)$. Removing as much as possible of $\pi(0, 2, 5)$ from D' without getting negative entries yields

$$D'' = D' - \frac{3}{10}\pi(0, 2, 5) = \begin{pmatrix} 1/5 & - & - \\ - & - & - \\ - & - & - \\ - & 1 & 4/5 \end{pmatrix}$$

Since $D'' = \frac{1}{5}\pi(0, 4, 5)$ we see that

$$\beta(A) = \frac{1}{2}\pi(0, 2, 3) + \frac{3}{10}\pi(0, 2, 5) + \frac{1}{5}\pi(0, 4, 5).$$

as in Example 2.5.

2.4. The boundary of $\Delta(\Pi_{\underline{d}, \vec{d}})$ and quasipure resolutions. The boundary of $\Delta(\Pi_{\underline{d}, \vec{d}})$ is given by all codimension one faces that are contained in precisely one facet. Each such face, F_i , defines a halfspace H_i and the intersection of these halfspaces defines a polytope

$$\cap_i H_i.$$

It is clear that $\cap_i H_i \subseteq \Delta(\Pi_{\underline{d}, \vec{d}})$, with equality if and only if $\Delta(\Pi_{\underline{d}, \vec{d}})$ is equal to the convex hull of $\Pi_{\underline{d}, \vec{d}}$. Hence to prove Conjecture 2.10 it is enough to prove that $\cap_i H_i = \Delta(\Pi_{\underline{d}, \vec{d}})$. Some of these halfspaces consists of all diagrams where a specific entry is non-negative and some do not.

Proposition 2.12. *Let $\pi = \pi(d_1) < \cdots < \pi(d_{i-1}) < \pi(d_i) < \pi(d_{i+1}) < \cdots < \pi(d_q)$ be a maximal chain in $\Pi_{\underline{d}, \bar{d}}$. Let F be the codimension one face in $\Delta(\Pi_{\underline{d}, \bar{d}})$ corresponding to the chain obtained by removing $\pi(d_i)$ from π . Then F belongs to the boundary of $\Delta(\Pi_{\underline{d}, \bar{d}})$ if and only if one of the following things hold:*

- a) $i = 1$ or $i = q$,
- b) d_{i-1} and d_{i+1} differ in only one position,
- c) d_{i-1} and d_{i+1} differ in two adjacent positions, say k and $k + 1$, and $(d_{i-1})_{k+1} = (d_{i-1})_k + 1$.

Furthermore, the faces obtained in this way from any two maximal chains containing $\pi(d_{i-1}) < \pi(d_i) < \pi(d_{i+1})$ corresponds to the same halfspace H , and in the case of a) and b) this halfspace consists of all diagrams in $V_{\underline{d}, \bar{d}}$ having a specific entry non-negative.

Proof. The face F belongs to the boundary of $\Delta(\Pi_{\underline{d}, \bar{d}})$ precisely when the facet π is the only facet containing F . This happens precisely when $\pi(d_i)$ is the only pure diagram that extends the chain F and we need to show that this happens only in the situations described in a), b) and c).

Since $\pi(d_1)$ and $\pi(d_q)$ are the unique minimal and maximal elements, respectively, in $\Pi_{\underline{d}, \bar{d}}$, removing one of them from π gives a face belonging to the boundary. This shows that F belongs to the boundary in the case of a). Assume that $i \neq 1$, $i \neq q$ and that

$$d_{i-1} = (a_1, \dots, a_p).$$

We have that d_{i-1} and d_{i+1} differ in at most two positions. If they differ in only one position, say k , then

$$d_{i+1} = (a_1, \dots, a_k + 2, \dots, a_p)$$

and there is only one element between d_{i-1} and d_{i+1} , namely

$$(a_1, \dots, a_k + 1, \dots, a_p).$$

If d_{i-1} and d_{i+1} differ in two positions, say k and l , then

$$d_{i+1} = (a_1, \dots, a_k + 1, \dots, a_l + 1, \dots, a_p)$$

and whenever $a_l \neq a_k + 1$, there are two elements between d_{i-1} and d_{i+1} , namely

$$(a_1, \dots, a_k + 1, \dots, a_l, \dots, a_p)$$

and

$$(a_1, \dots, a_k, \dots, a_l + 1, \dots, a_p).$$

If instead $a_l = a_k + 1$ then there is only one element between d_{i-1} and d_{i+1} and we must have $k = l + 1$ since the sequence is strictly increasing. Hence a), b) and c) are the only cases where we get a face belonging to the boundary of $\Delta(\Pi_{\underline{d}, \bar{d}})$.

Let π and π' be two maximal chains in $\Pi_{\underline{d}, \bar{d}}$ containing $\pi(d_{i-1}) < \pi(d_i) < \pi(d_{i+1})$. We know from Proposition 2.6 that the subchains of π and π' of all pure diagrams between $\pi(\underline{d})$ and $\pi(d_{i-1})$ span the same subspace of $V_{\underline{d}, \bar{d}}$, namely $V_{\underline{d}, d_{i-1}}$ and the same thing holds for the subchains of all pure diagrams between $\pi(d_{i+1})$ and $\pi(\bar{d})$. Hence, when we remove $\pi(d_i)$ from π and π' the remaining

pure diagrams in the two chains span the same subspace of $V_{\underline{d}, \bar{d}}$. Hence the two faces of $\Delta(\Pi_{\underline{d}, \bar{d}})$ defined by removing $\pi(d_i)$ from π and π' define the same halfspace.

In the case of a) and b), d_i has an entry in a position, say k , unique among all entries in position k of the other shifts in the chain. This means that if $D \in V_{\underline{d}, \bar{d}}$ then, since the chain π is a basis, D is a linear combination of the pure diagrams in π and the coefficient of $\pi(d_i)$ is zero precisely when $D_{k, (d_i)_k}$ is. This means that the subspace of $V_{\underline{d}, \bar{d}}$ spanned by the chain obtained by removing $\pi(d_i)$ from the chain π consists of the diagrams D such that $D_{k, (d_i)_k} = 0$. Hence the corresponding halfspace consists of all diagrams in which the entry in position $(k, (d_i)_k)$ is zero. $\square$

If a resolution has its Betti diagram in $B_{\underline{d}, \bar{d}}$, where $\bar{d}_{i-1} \leq \underline{d}_i$ for all $0 \leq i \leq p$, it is called *quasipure*. Herzog and Srinivasan showed in [6] that the multiplicity conjecture holds for quasipure resolutions. As a corollary to Proposition 2.11 we get that part of Conjecture 2.4 holds for a *strictly quasipure resolutions*, that is, resolutions with minimal and maximal shifts satisfying $\bar{d}_{i-1} < \underline{d}_i$ for all $0 \leq i \leq p$.

Corollary 2.13. *The Betti diagram of any Cohen-Macaulay module with strictly quasipure resolution is a non-negative linear combination of pure diagrams. In other words, if $\bar{d}_{i-1} < \underline{d}_i$ for all $0 \leq i \leq p$ then $\bar{B}_{\underline{d}, \bar{d}} \subseteq \Delta(\Pi_{\underline{d}, \bar{d}})$. It is also true, in this case, that $\Delta(\Pi_{\underline{d}, \bar{d}})$ is equal to the convex hull of $\Pi_{\underline{d}, \bar{d}}$.*

Proof. The point is that from the hypothesis on $\bar{d}$ and $\underline{d}$ it follows that the codimension one faces on the boundary of $\Delta(\Pi_{\underline{d}, \bar{d}})$ are all of the type described in a) and b) in Proposition 2.11. This means that if $H_1, H_2, \dots, H_t$ are the halfspaces corresponding to the faces on the boundary, then each H_i consists of all diagram in $V_{\underline{d}, \bar{d}}$ with a specific entry non-negative. Hence, every diagram in $V_{\underline{d}, \bar{d}}$ with all entries non-negative is in $\cap_i H_i$. Since each diagram in $\Pi_{\underline{d}, \bar{d}}$ have non-negative entries we see that $\Pi_{\underline{d}, \bar{d}} \subseteq \cap_i H_i$ and, as mentioned in the beginning of this section, this implies that the convex hull of $\Pi_{\underline{d}, \bar{d}}$ is equal to $\Delta(\Pi_{\underline{d}, \bar{d}})$. Finally, since the diagrams in $B_{\underline{d}, \bar{d}}$ have non-negative entries we get $\bar{B}_{\underline{d}, \bar{d}} \subseteq \cap_i H_i \subseteq \Delta(\Pi_{\underline{d}, \bar{d}})$. $\square$

2.5. Maximal Betti diagrams. Let $M = F/N$ be a Cohen-Macaulay R -module, where F is a free R -module and N a submodule of F . Then there is a lexicographic submodule L of F such that F/L and M have the same h -vector (see [12] and [7]). The Betti diagram of F/L is completely determined by the h -vector, $h(t)$, of M and of the free module F and we denote this diagram by $\beta_F^{\text{lex}}(h(t))$. The Betti numbers of M are smaller than the Betti numbers of F/L , and we even have that $\beta(M)$ is obtained from $\beta_F^{\text{lex}}(h(t))$ by a sequence of consecutive cancellations (see [16]). A consecutive cancellation is defined as follows. Let k and l be two integers and define a diagram $C^{k,l}$ by

$$(C^{k,l})_{i,j} = \begin{cases} 1 & \text{when } (i,j) = (k,l) \text{ or } (i,j) = (k+1,l), \\ 0 & \text{otherwise.} \end{cases}$$

A consecutive cancellation in position (k, l) of a diagram D is a diagram

$$D' = D - bC^{k,l},$$

where b is a non-negative rational number, and we assume that D' have no negative entries. Note that a consecutive cancellation does not change the polynomial $S_D(t) = \sum_{i,j} (-1)^i D_{i,j} t^j$, that is, $S_D(t) = S_{D'}(t)$, and hence not the h -vector or multiplicity of D . In short, for any Cohen-Macaulay R -module M with h -vector $h(t)$ we have that

$$(2.2) \quad \beta(M) = \beta_F^{\text{lex}}(h(t)) - \sum_{i,j} b_{i,j} C^{i,j}$$

for some non-negative integers $b_{i,j}$.

Let F be a free R -module with basis $e_1, e_2, \dots, e_t$ and assume that the basis of F is ordered by $e_1 < e_2 < \dots < e_t$ where $\deg e_1 \leq \deg e_2 \leq \dots \leq \deg e_t$. Let $H : \mathbb{Z} \rightarrow \mathbb{Z}$ be the Hilbert function of some submodule of F . Then, as mentioned above, there is a lexicographic submodule L with H as Hilbert function and we will now describe L . The monomials of F are the elements on the form ue_i for some monomial u of R and basis element e_i of F . The lexicographic order on monomials of F is given by $ue_i > ve_j$ when $i < j$ or when $i = j$ and $u > v$ in the lexicographic order on monomials of R . The lexicographic submodule L is generated in each degree d by the $H(d)$ largest monomials in F_d .

For any degree d , there are unique integers k and q such that $0 \leq q < H(R, d - \deg e_k)$ and

$$(2.3) \quad H(d) = \sum_{i=1}^{k-1} H(R, d - \deg e_i) + q.$$

For any F , H and d denote these numbers by $k(F, H, d) = k$ and $q(F, H, d) = q$ and furthermore let $g(F, H, d) = \deg e_k$. This means that L is generated in degree d by

$$\sum_{i=1}^{k-1} \mathfrak{m}^{d - \deg e_i} e_i + I e_k$$

where $k = k(F, H, d)$ and I is the ideal generated by the $q(F, H, d)$ largest monomials of degree $d - g(F, H, d)$ in R .

In what follows, let $e_{i,j}$, where $i = 1, 2, \dots, t$, $j = 1, 2, \dots, s$ and $\deg e_{i,j} = \deg e_i$, be a basis of F^s ordered by $e_{i,j} > e_{i',j'}$ when $i < i'$ or when $i = i'$ and $j > j'$, for any integer s .

Lemma 2.14. *Let N be a submodule of F such that the module $M = F/N$ is artinian. Then there is an integer s and a lexicographic submodule L of F^s such that L and N^s have the same h -vector, and L is on the form*

$$L = \sum_{j=1}^s \sum_{i=1}^t \mathfrak{m}^{c_{i,j}} e_{i,j}$$

where $c_{i,j}$ are non-negative integers.

Proof. Let H be the Hilbert function of M . To prove the lemma it is enough to show that there is a positive integer s such that $q(F^s, sH, d) = 0$ for all non-negative integers d . Note that in (2.3), $H(d) = H(F, d)$ implies $q = 0$, and hence that $H(d) = H(F, d)$ implies $q(F, H, d) = 0$. Since M is artinian, $H(d) \neq H(F, d)$ only for a finite number of integers and hence the same holds for $q(F, H, d)$. This means that there exists a positive integer s such that

$$(2.4) \quad s \frac{q(F, H, d)}{H(S, d - g(F, H, d))}$$

is an integer for all d . Let s be such an integer.

Fix a degree d and let $k = k(F, H, d)$ and $q = q(F, H, d)$ then we get by multiplying both sides of (2.3) by s ,

$$sH(d) = s \sum_{i=1}^{k-1} H(R, d - \deg e_i) + sq = \sum_{j=1}^s \sum_{i=1}^{k-1} H(R, d - \deg e_{i,j}) + sq$$

and since by (2.4), $sq = s'H(R, d - \deg e_k)$ for some $0 \leq s' < s$ we get

$$sH(d) = \sum_{j=1}^s \sum_{i=1}^{k-1} H(R, d - \deg e_{i,j}) + \sum_{i=j}^{s'} H(R, d - \deg e_{k,j}).$$

From the above equation it follows that $q(F^s, sH, d) = 0$ for all non-negative integers d . This means that L is generated in degree d by

$$\sum_{j=1}^s \sum_{i=1}^{k-1} \mathfrak{m}^{d - \deg e_{i,j}} e_{i,j} + \sum_{i=j}^{s'} \mathfrak{m}^{d - \deg e_{k,j}} e_{i,j}.$$

and since this holds for any degree d the lemma follows. $\square$

Proposition 2.15. *Let $M = F/N$ be an artinian R -module of codimension p with h -vector $h(t)$. Then there exist non-negative rational numbers $a_{i,j}$ and an integer s such that the diagram*

$$D = \sum_{i,j} a_{i,j} \beta(R/\mathfrak{m}^{j+1}(-\deg e_i))$$

have h -vector $h(t)$ and

$$\frac{1}{s} \beta_{F^s}^{\text{lex}}(sh(t)) = D.$$

As a consequence we get that $\beta(M)$ is obtained from D by a sequence of consecutive cancellations, that is,

$$\beta(M) = D - \sum_{i,j} b_{i,j} C^{i,j}$$

for some non-negative rational numbers $b_{i,j}$.

Proof. By Lemma 2.14 there is an integer s and a lexicographic submodule L of F^s such that F^s/L have h -vector $sh(t)$ and L is on the form

$$L = \sum_{j=1}^s \sum_{i=1}^t \mathfrak{m}^{c_{i,j}} e_{i,j}$$

where $c_{i,j}$ are non-negative integers. We get

$$\beta_{F^s}^{\text{lex}}(sh(t)) = \beta(F^s/L)$$

and since then

$$F^s/L = \bigoplus_{j=1}^s \bigoplus_{i=1}^t R/\mathfrak{m}^{c_{i,j}}(-\deg e_{i,j})$$

we see that

$$\beta_{F^s}^{\text{lex}}(sh(t)) = \sum_{j=1}^s \sum_{i=1}^t R/\mathfrak{m}^{c_{i,j}}(-\deg e_{i,j})$$

Collecting all the terms in the sum above where the $c_{i,j}$ and $\deg e_{i,j}$ are the same, yields

$$\beta_{F^s}^{\text{lex}}(sh(t)) = \sum_{i,j} a'_{i,j} \beta(R/\mathfrak{m}^{j+1}(-\deg e_i))$$

for some non-negative integers $a'_{i,j}$. Now, let $a_{i,j} = a'_{i,j}/s$ and $D = \beta_{F^s}^{\text{lex}}(sh(t))/s$.

Since the Hilbert function of M^s is $sh(t)$ we get that $\beta(M^s)$ is obtained from $\beta_{F^s}^{\text{lex}}(sh(t)) = sD$ by a sequence of consecutive cancellations, that is,

$$\beta(M^s) = sD - \sum_{i,j} b'_{i,j} C^{i,j}$$

for some non-negative integers $b_{i,j}$. Now $\beta(M^s) = s\beta(M)$ so dividing both sides of the equation above with s shows that $\beta(M)$ is obtained from D by a sequence of consecutive cancellations. $\square$

Corollary 2.16. *Let M be a Cohen-Macaulay module of codimension p generated in degrees $g_1, g_2, \dots, g_t$. Then the Betti diagram of M is given by*

$$\beta(M) = \sum_{i,j} a_{i,j} \pi(g_i, j+1, j+2, \dots, j+p) - \sum_{i,j} b_{i,j} C^{i,j},$$

for some non-negative rational numbers $a_{i,j}$ and $b_{i,j}$.

Proof. By artinian reduction we may assume that M is artinian. We may also assume that $M = F/N$ where F is a free module generated by $e_1, e_2, \dots, e_t$ such that $\deg e_i = g_i$ for $i = 1, 2, \dots, t$. By proposition 2.15 we get

$$\beta(M) = D - \sum_{i,j} b_{i,j} C^{i,j},$$

where

$$D = \sum_{i,j} a'_{i,j} \beta(R/\mathfrak{m}^{j+1}(-g_i)).$$

Since

$$\beta(R/\mathfrak{m}^{j+1-g_i}(-g_i)) = \pi(g_i, j+1, j+2, \dots, j+p)$$

the corollary follows if we let $a_{i,j} = a'_{i,j-g_i}$. $\square$

3. CODIMENSION ONE AND TWO

We will prove that Conjecture 2.4 and Conjecture 2.10 holds for Cohen-Macaulay R -modules of codimension one, with generators of any degrees, and for modules of codimension two, generated in a single degree.

The existence of R -modules with pure resolutions, of codimension one and two, of any type follows from the existence of compressed level modules.

Proposition 3.1. *If $d = (d_0, d_1, \dots, d_p)$ is a strictly increasing sequence of integers such that $d_i = d_1 + i - 1$ for all $1 \leq i \leq p - 1$, then there is a Cohen-Macaulay R -module with a pure minimal free resolution of type d .*

Proof. Let $S = k[x_1, x_2, \dots, x_p]$ and $s_i = \dim_k S_i$. Let t and t' be two positive integers and define

$$h_i = \min\{ts_i, t's_{c-i}\}$$

for each $0 \leq i \leq c$, where $c = d_p - p$. In earlier work, the first author showed the existence of compressed level modules in [1, Proposition 3.5], and hence that there is an artinian level S -module, M , with Hilbert function $i \mapsto h_i$ for any t and t' .

Let $t = s_{c-d_1+1}$ and $t' = s_{d_1-1}$ and let M be a compressed level S -module with Hilbert function $i \mapsto h_i$. Now it follows from [1, Proposition 4.1] that a minimal free resolution of M has shifts given by $d = (d_0, d_1, \dots, d_p)$. $\square$

Remark 3.2. In codimension one and two there are more explicit ways to construct modules with pure resolutions of any type, and these construction even gives multigraded modules. In codimension one everything is very simple. If $A = k[x]/x^{(d_1-d_0)}$ then $\beta(A(-d_0)) = \pi(d_0, d_1)$. In codimension two we can do the following. For any strictly increasing sequence of integers, (d_0, d_1, d_2) , let $a = (d_1 - d_0)(d_2 - d_1 - 1)$ and $b = (d_1 - d_0)(d_2 - d_1)$. Define two ideals of $k[x, y]$ by $I = (x^{a-i(d_1-d_0)}y^{i(d_1-d_0)})_{i=0}^{d_2-d_1-1}$ and $J = (x^{b-i(d_2-d_1)}y^{i(d_2-d_1)})_{i=0}^{d_1-d_0}$ and let M be the multigraded $k[x, y]$ -module $M = I/J$. Then $\beta(M(a - d_0)) = (d_2 - d_1)\pi(d_0, d_1, d_2)$.

With the existence part out of the way we turn to the problem of expanding Betti diagrams into pure diagrams. In codimension one, the set of possible Betti diagrams is easy to describe and it is then easy to see that any of them is a non-negative linear combination of pure diagrams. It turns out that the codimension two case then follows from the codimension one case. To see this we will need the following lemma.

For any sequence of integers $d = (d_0, d_1, \dots, d_{k-1}, d_k, d_{k+1}, \dots, d_p)$ denote by $\tau_k(d)$ the sequence $(d_0, d_1, \dots, d_{k-1}, d_{k+1}, \dots, d_p)$.

Lemma 3.3. *Let k be an integer such that $\bar{d}_k = \underline{d}_k$. Then there is an isomorphism of vector spaces*

$$\phi_k : V_{\underline{d}, \bar{d}} \rightarrow V_{\tau_k(\underline{d}), \tau_k(\bar{d})}$$

given by

$$\phi_k(D)_{i,j} = |\bar{d}_k - j| \cdot \begin{cases} D_{i,j} & \text{when } i < k, \\ D_{i+1,j} & \text{otherwise,} \end{cases}$$

for any diagram $D \in V_{\underline{d}, \bar{d}}$.

Proof. First we need to prove that $\phi_k(D)$ is a diagram of projective dimension $p-1$ and by definition this is equivalent to $\frac{d^i}{dt^i} S_{\phi_k(D)}(1) = 0$ for $i = 0, 1, \dots, p-2$. The key observation here is that

$$S_{\phi_k(D)}(t) = \bar{d}_k S_D(t) - \frac{d}{dt} S_D(t).$$

In fact, since $S_D(t) = \sum_{i,j} (-1)^i D_{i,j} t^j$ and $\frac{d}{dt} S_D(t) = \sum_{i,j} (-1)^i j D_{i,j} t^{j-1}$ we get

$$\bar{d}_k S_D(t) - \frac{d}{dt} S_D(t) = \sum_{i,j} (-1)^i (\bar{d}_k - j) D_{i,j} t^j.$$

Now

$$(\bar{d}_k - j) D_{i,j} = \begin{cases} |\bar{d}_k - j| D_{i,j} & \text{when } i < k, \\ 0 & \text{when } i = k, \\ -|\bar{d}_k - j| D_{i,j} & \text{when } i > k, \end{cases}$$

simply because $D_{i,j} = 0$ whenever $j < \underline{d}_i$ or $j > \bar{d}_i$, and since by assumption $\bar{d}_k = \underline{d}_k$. Finally, we get

$$\begin{aligned} & \sum_j \sum_{i=0}^p (-1)^i (\bar{d}_k - j) D_{i,j} t^j \\ &= \sum_j \left(\sum_{i=0}^{k-1} (-1)^i |\bar{d}_k - j| D_{i,j} t^j + \sum_{i=k+1}^p (-1)^{i+1} |\bar{d}_k - j| D_{i,j} t^j \right) \\ &= \sum_j \sum_{i=0}^{p-1} (-1)^i \phi_k(D)_{i,j} t^j = S_{\phi_k(D)}(t). \end{aligned}$$

Since the pure diagrams span $V_{\tau_k(\underline{d}), \tau_k(\bar{d})}$ and any pure diagram, clearly, is in the image of ϕ_k we see that ϕ_k is surjective. That ϕ_k is an isomorphism follows, for example, from the fact that $\dim V_{\underline{d}, \bar{d}} = 1 + \sum_{i=0}^p \bar{d}_i - \underline{d}_i = 1 + \sum_{i \neq k} \bar{d}_i - \underline{d}_i = \dim V_{\tau_k(\underline{d}), \tau_k(\bar{d})}$. $\square$

Theorem 3.4. *Let M be a Cohen-Macaulay R -module of codimension one, generated in any degrees, or of codimension two, generated in a single degree. Then the Betti diagram of M is a non-negative linear combination of pure diagrams from the same chain and furthermore, any pure diagram of codimension one or two is a rational multiple of the Betti diagram of some Cohen-Macaulay R -module. In other words, when $p = 1$ or when $p = 2$ and $\underline{d}_0 = \bar{d}_0$ then*

$$\bar{B}_{\underline{d}, \bar{d}} = \Delta(\Pi_{\underline{d}, \bar{d}}).$$

Proof. The existence of R -modules of codimension one or two, with pure resolutions of any type was proven in Proposition 3.1.

To prove the rest of the theorem we start with the codimension one case. Let D be a diagram of codimension one. Since for any shifts (d_0, d_1) the pure diagram $\pi(d_0, d_1)$ has as its non-zero entries $\pi(d_0, d_1)_{0, d_0} = 1$ and $\pi(d_0, d_1)_{1, d_1} =$

1 we see that D is a non-negative linear combination of pure diagrams if and only if

$$(3.1) \quad D_{i,j} \geq 0$$

for all integers i and j , and

$$(3.2) \quad \sum_{i \leq l} D_{0,i} \leq \sum_{i \leq l} D_{1,i+1}$$

for each integer l . Furthermore, if D satisfies (3.1) and (3.2) it will be a non-negative linear combination of pure diagrams from the same chain. To see this let (d_0, d_1) be the minimal shifts of D and let c be the largest rational number such that all entries of $D' = D - c\pi(d_0, d_1)$ are non-negative. Then D' satisfy (3.1) and (3.2) and the minimal shifts of D' are larger than (d_0, d_1) . By induction on the minimal shifts we may assume that D' , and hence D , is a non-negative linear combination of pure diagrams from the same chain.

Let M be a Cohen-Macaulay R -module of codimension one. By Corollary 2.16 the Betti diagram of M can be obtained from a non-negative linear combination of pure diagrams by a sequence of consecutive cancellations. Since a consecutive cancellation does not change the properties (3.1) and (3.2) already enjoyed by any non-negative linear combination, we see that the Betti diagram of M also satisfies (3.1) and (3.2) and hence is a non-negative linear combination of pure diagrams from the same chain.

We now turn to the codimension two case. Let M be a Cohen-Macaulay R -module of codimension two, generated in a single degree. We may, without loss of generality, assume that M is generated in degree zero. By Corollary 2.16 we then have $\beta(M) = \sum_j a_j \pi(0, j+1, i+2) - \sum_j b_j C^{1,j}$. Using the isomorphism ϕ_0 from Lemma 3.3 and the fact that $\phi_0(\pi(0, j+1, j+2)) = a \pi(j+1, j+2)$, for some rational number a , and $\phi_0(C^{1,j}) = j C^{0,j}$, we get $\phi_0(\beta(M)) = \sum_j a'_j \pi(j+1, j+2) - \sum_j b_j j C^{0,j}$. We see that $\phi_0(\beta(M))$ is obtained from a non-negative linear combination of pure diagrams by a sequence of consecutive cancellations, and since $\phi_0(\beta(M))$ is of codimension one, it is, by the same argument as above, a non-negative linear combination of pure diagrams from the same chain. Finally, ϕ_0 is a linear map that preserves chains of pure diagrams and the same thing holds for its inverse ϕ_0^{-1} . Since $\beta(M) = \phi_0^{-1}(\phi_0(\beta(M)))$ we get that $\beta(M)$ is a non-negative linear combination of pure diagrams from the same chain. $\square$

As a corollary we get, using Proposition 2.8, that the Multiplicity conjecture holds for Cohen-Macaulay R -modules of codimension two, generated in a single degree. In [13] the upper bound of the conjecture was shown to hold for codimension two modules with generators of any degrees.

Corollary 3.5. *If M is a Cohen-Macaulay R -module of codimension two, generated in a single degree, with minimal and maximal shifts given by $(d_0, \underline{d}_1, \underline{d}_2)$ and $(d_0, \bar{d}_1, \bar{d}_2)$ respectively, then*

$$\beta_0(M) \frac{(\underline{d}_1 - d_0)(\underline{d}_2 - d_0)}{2} \leq e(M) \leq \beta_0(M) \frac{(\bar{d}_1 - d_0)(\bar{d}_2 - d_0)}{2}.$$

4. HIGHER CODIMENSION

In this section we will show that the Betti diagram of a Cohen-Macaulay algebra A , that is, $A = R/I$ for some ideal I of R , is a non-negative linear combination of pure diagrams when A is a complete intersection, of any codimension, or a Gorenstein algebra of codimension three. The proofs of these two cases have some steps in common and we will start by explaining these common steps.

Both proofs work by breaking down the Betti diagram into a sum of two Betti diagrams whose codimension is the codimension of the original diagram minus one. Let E and F be two diagrams of codimension $p-1$ such that $e(E) = e(F)$. Then we claim that D , defined by

$$D_{i,j} = E_{i,j} + F_{i-1,j},$$

is a diagram of codimension p . (Note that D is the sum of the matrix E and the matrix obtained from F by shifting its columns one step to the right.) To prove that D is a diagram of codimension p we need to prove that the polynomial $S_D(t)$ is divisible by $(1-t)^p$. We have

$$S_D(t) = \sum_{i,j} (-1)^i D_{i,j} t^j = \sum_{i,j} (-1)^i E_{i,j} t^j + \sum_{i,j} (-1)^i F_{i-1,j} t^j = S_E(t) - S_F(t).$$

Since E and F are diagrams of codimension $p-1$ we know that $S_E(t)$ and $S_F(t)$ are divisible by $(1-t)^{p-1}$ and by definition $h_E(t) = S_E(t)/(1-t)^{p-1}$ and $h_F(t) = S_F(t)/(1-t)^{p-1}$. Hence $S_D(t)/(1-t)^{p-1} = h_E(t) - h_F(t)$ and it remains to prove that $t=1$ is a root of $h_E(t) - h_F(t)$. This follows from the fact that by definition $e(E) = h_E(1)$ and $e(F) = h_F(1)$ and by assumption $e(E) = e(F)$.

Now assume that E and F are non-negative linear combinations of pure diagrams. We will show that if the pure diagrams in these two non-negative linear combinations fit together in a certain way, then the diagram D is a non-negative linear combination of pure diagrams. How two pure diagrams should fit together is described in the following lemma.

Lemma 4.1. *Let $d = (d_0, d_1, \dots, d_p)$ and $d' = (d'_0, d'_1, \dots, d'_p)$ be two strictly increasing sequences of integers such that $d_i < d'_i$ for $i = 0, 1, \dots, p$ and define D by*

$$D_{i,j} = \pi(d)_{i,j} + \frac{e(\pi(d))}{e(\pi(d'))} \pi(d')_{i-1,j}.$$

Then D is a non-negative linear combination of pure diagrams of codimension $p+1$

Proof. We may assume, without loss of generality, that $d_0 = 0$. The proof is by induction on the codimension p . If $p = 1$, then D is simply a pure diagram of codimension two with shifts (d_0, d'_0) , so the assertion of the lemma is true in this case. Assume now that $p > 1$. Let $\pi = \pi(d_0, d_1, \dots, d_p, d'_p)$ and

$$E = D - \frac{(d'_p - d_p)}{d'_p} \pi.$$

Furthermore, let ϕ be the map from Lemma 3.3 defined by $\phi(E)_{i,j} = (d'_p - j)E_{i,j}$. We will now show that

$$\phi(E)_{i,j} = d_p \pi(\tau(d))_{i,j} + \frac{e(\pi(d))}{e(\pi(d'))} d'_p \pi(\tau(d'))_{i-1,j},$$

where $\tau(d) = (d_0, d_1, \dots, d_{p-1})$ and $\tau(d') = (d'_0, d'_1, \dots, d'_{p-1})$. Denote by ρ the matrix defined by $\rho_{i,j} = \pi(d')_{i-1,j}$. Then we have

$$\phi(\rho)_{i,j} = (d'_p - j)\rho_{i,j} = (d'_p - j)\pi(d')_{i-1,j}.$$

Since $\pi(d')_{i,d'_i} = (-1)^i \prod_{j \neq i} \frac{d'_i - d'_0}{d'_i - d'_j}$ we see that $(d'_p - j)\pi(d')_{i-1,j} = (d'_p - d'_0)\pi(\tau(d'))_{i-1,j}$ and hence that

$$\phi(\rho)_{i,j} = (d'_p - d'_0)\pi(\tau(d'))_{i-1,j}.$$

In the same way we see that

$$\phi(\pi)_{i,j} = d'_p \pi(d)_{i,j}.$$

Hence,

$$\begin{aligned} \phi(\pi(d))_{k,d_k} - \frac{(d'_p - d_p)}{d'_p} \phi(\pi)_{k,d_k} &= (d'_p - d_k)\pi(d)_{k,d_k} - (d'_p - d_p)\pi(d)_{k,d_k} = \\ &= (d_p - d_k)\pi(d)_{k,d_k} = d_p \pi(\tau(d))_{k,d_k}. \end{aligned}$$

and we get

$$\phi(E)_{i,j} = d_p \pi(\tau(d))_{i,j} + \frac{e(\pi(d))}{e(\pi(d'))} (d'_p - d'_0)\pi(\tau(d'))_{i-1,j}.$$

Note that $\frac{e(\pi(d))(d'_p - d'_0)}{e(\pi(d'))d_p} = \frac{e(\pi(\tau(d)))}{e(\pi(\tau(d')))} and hence that $\phi(E)$ is a sum of two pure diagrams in the same way D was, but now the pure diagrams have codimension $p - 1$. By induction we may assume that $\phi(E)$ is a non-negative linear combination of pure diagrams of codimension p . By using the inverse of ϕ we see that E is a non-negative linear combination of pure diagrams and hence that D is, since $D = E + (d'_p - d_p)/d'_p \pi$ and $d'_p - d_p > 0$. $\square$$

Example 4.2. Let $d = (0, 2, 3)$ and $d' = (1, 3, 5)$. Then

$$\pi(d) = \begin{pmatrix} 1 & - & - \\ - & 3 & 2 \end{pmatrix} \text{ and } \pi(d') = \begin{pmatrix} - & - & - \\ 1 & - & - \\ - & 2 & - \\ - & - & 1 \end{pmatrix}$$

and for the multiplicities we have $e(\pi(d)) = 3$ and $e(\pi(d')) = 4$. The diagram

$$D_{i,j} = \pi(d)_{i,j} + \frac{e(\pi(d))}{e(\pi(d'))} \pi(d')_{i-1,j}.$$

of Lemma 4.1 is then

$$D = \begin{pmatrix} 1 & - & - & - \\ - & 3 & 2 & - \\ - & - & - & - \end{pmatrix} + \frac{3}{4} \begin{pmatrix} - & 1 & - & - \\ - & - & 2 & - \\ - & - & - & 1 \end{pmatrix} = \begin{pmatrix} 1 & 3/4 & - & - \\ - & 3 & 7/2 & - \\ - & - & - & 3/4 \end{pmatrix}$$

and the non-negative linear expansion of D into pure diagrams whose existence is guaranteed by Lemma 4.1 is

$$D = \frac{2}{5}\pi(0, 1, 3, 5) + \frac{3}{5}\pi(0, 2, 3, 5).$$

4.1. Complete intersections. Let I be an ideal in R such that R/I is a complete intersection, that is, $I = (f_1, f_2, \dots, f_p)$ where $f_1, f_2, \dots, f_p$ is a regular sequence in R .

Theorem 4.3. *The Betti diagram of a complete intersection, R/I , is a non-negative linear combination of pure diagrams.*

Proof. Denote by I' the ideal $(f_1, f_2, \dots, f_{p-1})$. Then it follows from the Koszul resolutions of R/I and R/I' that

$$(4.1) \quad \beta_{i,j}(R/I) = \beta_{i,j}(R/I') + \beta_{i-1,j-d}(R/I')$$

where d is the degree of f_p . By induction, on the codimension, we may assume that

$$\beta(R/I') = \sum_{k=1}^d a_k \pi(d_k)$$

for some pure diagrams $\pi(d_1), \pi(d_2), \dots, \pi(d_s)$ and some non-negative rational numbers $a_1, a_2, \dots, a_s$. By (4.1) we get

$$\beta(R/I) = \sum_{i=k}^s a_k \rho_k$$

where ρ_k is defined by

$$(\rho_k)_{i,j} = \pi(d_k)_{i,j} + \pi(d_k)_{i-1,j-d}.$$

Hence, to prove that $\beta(R/I)$ is a non-negative linear combination of pure diagrams it is enough to prove that ρ_k is, for $k = 1, 2, \dots, s$. Assume that $d_k = (d_0, d_1, \dots, d_p)$. Then $\pi(d_k)_{i-1,j-d} = \pi(d + d_0, d + d_1, \dots, d + d_p)_{i-1,j}$ and we get

$$(\rho_k)_{i,j} = \pi(d_0, d_1, \dots, d_p)_{i,j} + \pi(d + d_0, d + d_1, \dots, d + d_p)_{i-1,j}.$$

Since the two pure diagrams in the sum giving ρ_k both have multiplicity $d_1 d_2 \cdots d_p$ and clearly $d_i < d + d_i$ for each $i = 0, 1, \dots, p$, we get, by Lemma 4.1, that ρ_k is a non-negative linear combination of pure diagrams. $\square$

4.2. Gorenstein algebras of codimension three.

Theorem 4.4. *Let $A = R/I$ be a Gorenstein algebra of codimension three for some ideal I in R . Then the Betti diagram of A is a non-negative linear combination of pure diagrams, all from the same chain.*

Proof. Let I be a height three Gorenstein ideal in R and let

$$0 \rightarrow R(-f) \rightarrow \bigoplus_{i=1}^{2k+1} R(-f + a_i) \rightarrow \bigoplus_{i=1}^{2k+1} R(-a_i) \rightarrow R \rightarrow R/I \rightarrow 0$$

be a minimal free resolution, where $a_1 \leq \dots \leq a_{2k+1}$. From Geramita and Migliore [4] we know that there is a height two ideal, I_C , with minimal free resolution

$$0 \rightarrow \bigoplus_{i=k+2}^{2k+1} R(-f + a_i) \rightarrow \bigoplus_{i=1}^{k+1} R(-a_i) \rightarrow R \rightarrow R/I_C \rightarrow 0.$$

Let $F_0 = R$, $F_1 = \bigoplus_{i=1}^{k+1} R(-a_i)$ and $F_2 = \bigoplus_{i=k+2}^{2k+1} R(-f + a_i)$. Then, numerically, we can write the resolution of R/I as

$$\begin{array}{ccccccc} 0 & \longrightarrow & F_0(-f) & \longrightarrow & F_1(-f) & \longrightarrow & F_2(-f) \\ & & \oplus & & \oplus & & \oplus \\ & & 0 & \longrightarrow & F_2 & \longrightarrow & F_1 & \longrightarrow & F_0 \end{array}$$

From Theorem 3.3 we know that the Betti diagram of the resolution $0 \rightarrow F_2 \rightarrow F_1 \rightarrow F_0$ is a non-negative linear combination of pure diagrams. These pure diagrams then have shifts $(0, a_i, f - a_j)$, for some $1 \leq i \leq k + 1$ and $k + 2 \leq j \leq 2k + 1$, such that $a_i \leq f - a_j$. Hence the Betti diagram of $0 \rightarrow F_2 \rightarrow F_1 \rightarrow F_0$ is

$$\sum_{i,j} b_{i,j} \pi(0, a_i, f - a_j).$$

for some non-negative rational numbers $b_{i,j}$.

Let $\pi = \pi(0, a_i, f - a_j)$ be such a diagram and define a diagram $D(i, j)$ by

$$D(i, j)_{k,l} = \pi(0, a_i, f - a_j)_{k,l} + \frac{a_i}{a_i + a_j - f} \pi(a_j, f - a_i, f)_{k-1,l}.$$

The Betti diagram of R/I is then

$$\sum_{i,j} b_{i,j} D(i, j),$$

so all we have to do is to show that $D(i, j)$ is a non-negative linear combination of pure diagrams. By Lemma 4.1, $D(i, j)$ is a non-negative linear combination of pure diagrams if the two diagrams in the sum giving $D(i, j)$ have the same multiplicity and $0 < a_j$, $a_i < f - a_i$ and $f - a_j < f$. Both diagrams have multiplicity $a_i(f - a_j)$ so the only thing left to check here is that $a_i < f - a_i$ for $i = 1, \dots, k + 1$. Let $r_i = f - 2a_i$ and note that $r_1 \geq \dots \geq r_{2k+1}$. We know from [3, Proposition 3.1] that

$$r_i + r_{2k+3-i} > 0, \text{ for } i = 2, \dots, k + 1.$$

Now we have

$$r_{k+1} - r_{k+2} \geq 0$$

and

$$r_{k+1} + r_{k+2} > 0$$

and we get

$$r_1 \geq \dots \geq r_{k+1} > 0$$

which then implies $a_i < f - a_i$ for $i = 1, \dots, k + 1$.

It remains to prove that the pure diagrams in the non-negative linear combination can be taken all from the same chain. The minimal and maximal

shifts of A are $\underline{d} = (0, a_1, f - a_{2k+1}, f)$ and $\overline{d} = (0, a_{2k+1}, f - a_1, f)$. Since $\overline{d}_3 = \underline{d}_3 = f$, Lemma 3.3 gives an isomorphism $\phi_3 : V_{\underline{d}, \overline{d}} \rightarrow V_{\tau_3(\underline{d}), \tau_3(\overline{d})}$ where $\tau_3(\underline{d}) = (0, a_1, f - a_{2k+1})$ and $\tau_3(\overline{d}) = (0, a_{2k+1}, f - a_1)$. Since $\beta(A)$ is a non-negative linear combination of pure diagrams, the same is true for $\phi_3(\beta(A))$ since ϕ_3 preserves non-negative linear combinations of pure diagrams. From Theorem 3.4 we get, since $\phi_3(\beta(A))$ has codimension two, that the pure diagrams in the non-negative linear combination giving $\phi_3(\beta(A))$ can be chosen from the same chain. Since ϕ_3 preserves chains of pure diagrams we get that $\beta(A)$ is a non-negative linear combination of pure diagram all from the same chain. $\square$

ACKNOWLEDGEMENTS

We would like to thank Fabrizio Zanello for introducing us to the Multiplicity conjecture.
